Introduction to Combustion in Propellants and Explosives

Combustion, in the context of propellants and explosives, refers to the rapid chemical reaction that releases gases, heat, and energy in a controlled or uncontrolled manner. Propellants are designed to produce a sustained, controlled burn^{used in rockets, firearms, and missiles}while explosives are characterized by their ability to generate a shock wave and produce a violent, often instantaneous, release of energy.

The key distinctions between the two types include:

- Propellants: Typically involve slower, controlled combustion or deflagration, with the aim of producing thrust or sustained pressure.
- Explosives: Undergo rapid, often detonation-based, energy release characterized by shock wave propagation.

Understanding the phenomena involved in their combustion is essential for optimizing performance, ensuring safety, and minimizing unintended consequences.

Fundamental Phenomena in Combustion of Propellants and Explosives

Several phenomena underpin the behavior and performance of propellants and explosives during combustion:

Ignition and Initiation

Ignition marks the onset of combustion, typically triggered by heat, friction, shock, or chemical stimuli. The initiation phase is critical because it determines whether the energetic material will undergo controlled combustion or an uncontrolled explosion.

- Chemical Initiation: Heat or electrical sparks provide the energy to surpass the activation barrier.
- Mechanical Initiation: Shock waves or impact can induce localized heating and chemical reactions.
- Controlling Factors: Composition, temperature, pressure, and environmental conditions influence ignition sensitivity.

Key phenomena during initiation include:

- Localized heating leading to the formation of reactive intermediates.
- Formation of hot spots, which are localized regions with elevated temperature that can serve as ignition points.
- Shock-wave interaction, especially in explosives, where shock compression can accelerate reactions.

Flame Propagation

Once ignited, the combustion process propagates through the material as a flame front. The nature of this propagation significantly influences the overall performance.

Types of flame propagation:

- Deflagration: Subsonic combustion wave driven by heat transfer and mass diffusion.
- Detonation: Supersonic shock-driven combustion wave characterized by a coupled shock and reaction zone.

Factors affecting flame propagation include:
