Working Principle

The core of the FM transmitter is the oscillator circuit, which generates a carrier wave at a specific frequency. The audio signal modulates this carrier through frequency modulation, altering the carrier's frequency proportional to the audio signal's amplitude.

Detailed Circuit Description

Oscillator Circuit

The oscillator is typically a Colpitts or Hartley oscillator, utilizing a transistor, inductor, and capacitor to produce a high-frequency sine wave. The frequency is determined by the tank circuit composed of an inductor and capacitor.

Modulation Circuit

The audio input is fed into the oscillator circuit to cause variations in the oscillator's frequency, effectively encoding the audio onto the RF carrier. The modulation index depends on the amplitude of the input audio and the oscillator design.

Output Stage

The modulated RF signal is taken from the collector or drain of the transistor and is transmitted via an antenna, allowing wireless reception.

Design Calculations

Proper calculations ensure the transmitter operates at the desired frequency and with appropriate modulation characteristics.

- **Resonant Frequency (f):** determined by $f = \frac{1}{2\pi \sqrt{LC}}$
- **Inductor (L):** chosen based on the desired frequency and capacitor value.
- **Capacitor (C):** variable to fine-tune the frequency.

Implementation and Testing

Assembly Process

- Assemble the circuit on a breadboard for initial testing.
- Connect the power supply and ensure all connections are correct.
- Use a function generator or microphone for audio input.
- Attach the antenna to the output terminal for transmission.

Testing Procedure

- Power on the transmitter and adjust the variable capacitor to tune to the desired frequency.
- Use an FM receiver to tune into the transmitted frequency.
- Play audio signals and observe the modulation quality.
