oxidation of primary and secondary alcohols to aldehydes, ketones, and carboxylic acids using reagents like PCC, Jones reagent, and oxidizing agents like KMnO_4 , as well as reductions using NaBH_4 , LiAlH_4 , and catalytic hydrogenation. What are key reactions involved in aromatic substitution that are important for the exam? Important reactions include electrophilic aromatic substitution such as nitration, sulfonation, halogenation, Friedel-Crafts alkylation and acylation, and the directing effects of substituents. How important are the reactions involving carbonyl compounds in the ACS Organic Exam? Very important; reactions include nucleophilic addition to aldehydes and ketones, acetal formation, enolate chemistry, aldol condensations, and reactions involving reduction and oxidation of carbonyl groups. Which types of polymerization reactions are frequently tested in the exam? Commonly tested polymerization reactions include free radical polymerization (e.g., styrene, methyl methacrylate), addition polymerization, and the basic mechanisms involved. What are the typical reactions involved in the synthesis of alcohols, amines, and ethers? Reactions include nucleophilic substitution ($\text{S}_\text{N}2$, $\text{S}_\text{N}1$), reduction of carbonyl compounds, Williamson ether synthesis, and Gabriel synthesis for amines. Are there specific pericyclic reactions that are important for the ACS Organic Exam? Yes, key pericyclic reactions include Diels-Alder cycloaddition, electrocyclic reactions, sigmatropic rearrangements, and cycloaddition mechanisms. What are the crucial reactions involving stereochemistry that students should focus on? Important reactions involve stereoselective and stereospecific reactions such as $\text{S}_\text{N}2$, E2, additions to chiral alkenes, and the mechanisms of chiral synthesis, including enolate chemistry and asymmetric catalysis. How relevant are rearrangement reactions like the Wagner-Meerwein or Baeyer-Villiger in the exam? Rearrangement reactions such as Wagner-Meerwein, Baeyer-Villiger oxidation, and pinacol rearrangement are frequently tested as they are fundamental to understanding reaction pathways and mechanisms. What are the key reactions involving the formation and cleavage of protecting groups in organic synthesis? Important reactions include the formation of silyl ethers for alcohol protection, acetal and ketal formation for carbonyl protection, and their subsequent deprotection methods, such as acid hydrolysis.
